

# Numerical Computing: Background

Prepared for the Bank of Portugal Computational Economics  
Course

John Stachurski

October 2025

# Topics

- Low level languages
- Interpreted code
- Array processing
- JIT compilation

# History: Setting the stage

Let's briefly discuss the evolution of scientific computing

Let's recall some of the major paradigms and ideas:

- Languages and compilers
- Dynamic and static types
- Background on vectorization / JIT compilers

## Fortran / C — static types and AOT compilers

**Example.** Suppose we want to compute the sequence

$$k_{t+1} = sk_t^\alpha + (1 - \delta)k_t$$

from some given  $k_0$

Let's write a function in C that

1. implements the loop
2. returns the last  $k_t$

```
int main() {  
    double k = 0.2;  
    double alpha = 0.4;  
    double s = 0.3;  
    double delta = 0.1;  
    int i;  
    int n = 1000;  
    for (i = 0; i < n; i++) {  
        k = s * pow(k, alpha) + (1 - delta) * k;  
    }  
    printf("k = %f\n", k);  
}
```

First we compile the whole program (ahead-of-time compilation):

```
>> gcc solow.c -o out -lm
```

Now we execute:

```
>> ./out
```

```
x = 6.240251
```

## Pros

- fast arithmetic
- fast loops

## Cons

- slow to write
- lack of portability
- hard to debug
- hard to parallelize
- low interactivity

For comparison, the same operation in Python:

```
 $\alpha$  = 0.4  
s = 0.3  
 $\delta$  = 0.1  
n = 1_000  
k = 0.2  
  
for i in range(n-1):  
    k = s * k** $\alpha$  + (1 -  $\delta$ ) * k  
  
print(k)
```

Python is **interpreted** rather than compiled

- code is executed statement by statement
- data types are queried on the fly
- arithmetic operations require method resolution

## Pros

- easy to write
- high portability
- immediate feedback — high interactivity
- easy to debug

## Cons

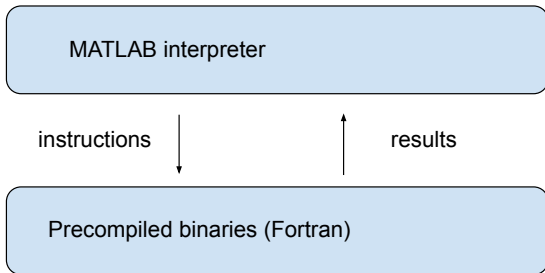

- slow

So how can we get

good execution speeds **and** high productivity / interactivity?

# MATLAB

“MATLAB is Fortran for the 1990s!”

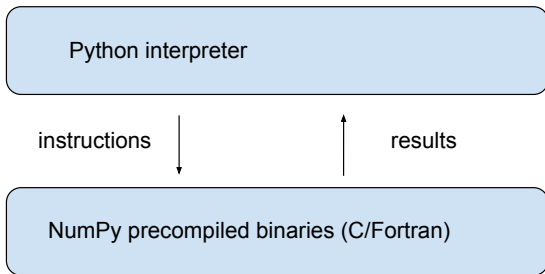

```
A = [2.0, -1.0  
      5.0, -0.5];
```

```
b = [0.5, 1.0]';
```

```
x = inv(A) * b
```

# Python + NumPy

Open source MATLAB-like array operations within Python

```
import numpy
```

```
A = ((2.0, -1.0),  
      (5.0, -0.5))
```

```
b = (0.5, 1.0)
```

```
A, b = np.array(A), np.array(b)
```

```
x = np.inv(A) @ b
```

1. Arrays defined with high-level commands
  - (Python / NumPy API)
2. Execution takes place in an efficient low-level environment
  - Efficient machine code (compiled C / Fortran)
3. Results are returned to the high-level interface

## Advantages of NumPy / MATLAB

- Operations are passed to specialized machine code
- Type-checking is **paid per array, not per array element**

## Disadvantages

- Memory intensive (generates intermediate arrays)
- Limited — how to accelerate the Solow code using NumPy?
- Specializes on **types** but not on **shapes**

The last point is important for modern hardware...

# Julia — rise of the JIT compilers

Can do MATLAB / NumPy style vectorized operations

```
A = [2.0  -1.0  
     5.0  -0.5]
```

```
b = [0.5  1.0]'
```

```
x = inv(A) * b
```

But also has fast loops via an efficient JIT compiler

**Example.** Suppose, again, that we want to compute

$$k_{t+1} = sk_t^\alpha + (1 - \delta)k_t$$

from some given  $k_0$

- Iterative, not easily vectorized

```
function solow(k0, α=0.4, δ=0.1, n=1_000)
    k = k0
    for i in 1:(n-1)
        k = s * k^α + (1 - δ) * k
    end
    return k
end

solow(0.2) # JIT-compiled at first call
```

Julia accelerates solow at runtime via a JIT compiler

## Pros:

- fast execution — assuming correct type inference
- dynamically typed...(but compiler wants type stability)
- elegant: close to the maths

## Cons:

- Everything compiled might not be optimal
  - debugging is more challenging
  - slow first runs
- Repeated breaking changes and package instability
- Parallelization not well automated

## Python + Numba — same architecture, same speed

```
from numba import jit

@jit(nopython=True)
def solow(k0,  $\alpha=0.4$ ,  $\delta=0.1$ , n=1_000):
    k = k0
    for i in range(n-1):
        k = s * k** $\alpha$  + (1 -  $\delta$ ) * k
    return k

solow(0.2)
```

Runs at same speed as Julia / C / Fortran

# New Paradigms

The technologies discussed above are all more than 10 years old

Recently developed coding environments tend to be oriented towards AI

- PyTorch
- Google JAX
- Mojo, etc.

Sometimes these new environments are better...and sometimes not

We will discuss them later in the course
